Question: 654

In the context of security, how does Podman enhance container security compared to Docker?

- A. Podman does not require a root user to run containers, allowing for improved security posture.
- B. Podman uses a centralized daemon for managing containers, providing better security.
- C. Podman is limited to user namespaces, while Docker supports multiple security features.
- D. Podman cannot run containers as root, limiting its functionality.

Answer: A

Explanation: Podman enhances security by allowing containers to be run as non-root users, reducing the risk of privilege escalation and improving the overall security posture.

Question: 655

If you are tasked with optimizing a Packer image build process to minimize build times, which of the following techniques would be most effective, particularly in a cloud environment where network latency can impact performance?

- A. Use a single provisioner for all tasks
- B. Implement parallel builds where possible
- C. Always use the latest base image
- D. Limit the number of provisioners to reduce complexity

Answer: B

Explanation: Implementing parallel builds allows multiple images to be built simultaneously, significantly reducing overall build times, especially in environments where network and resource constraints can slow down individual builds.

Question: 656

Which of the following would be the best approach to troubleshoot network connectivity issues between two Xen domains?

- A. Check the XenStore configuration for both domains.
- B. Increase the memory allocation for both domains.
- C. Restart the Xen hypervisor.
- D. Verify the network bridge configuration and ensure proper vif settings.
